Outline

1. Joint Action - acting together

Investigating **real-time** social interactions

2. Music - unique human cultures

How does studying music help to understand social interactions?

3. My research: teaching expertise

How has social learning contributed to cultural transmission?

1. Joint Action

acting together

What is Joint Action (JA)?

- A variety of **real-time** communication and coordination in our daily life.
- Is studying individuals enough to understand social interactions?

Working definitions

- ...any form of social interaction whereby **two or more individuals coordinate their actions in space and time** to bring about a change in the environment (Sebanz et al., 2006)
- SCA (Shared Cooperative Activity) involves mutual responsiveness—of intention and in action—in the service of appropriately stable, interlocking, reflexive, and **mutually noncoerced intentions in favor of the joint activity** (Bratman, 1992)
- ...there is in fact a range of **different levels of 'joint'** behaviour (Milward & Carpenter, 2018)

Comparison between individual and joint performances

- Do people behave differently when they are doing the same task with or without a partner?
- One of the well-established psychological effects: **Simon effect**

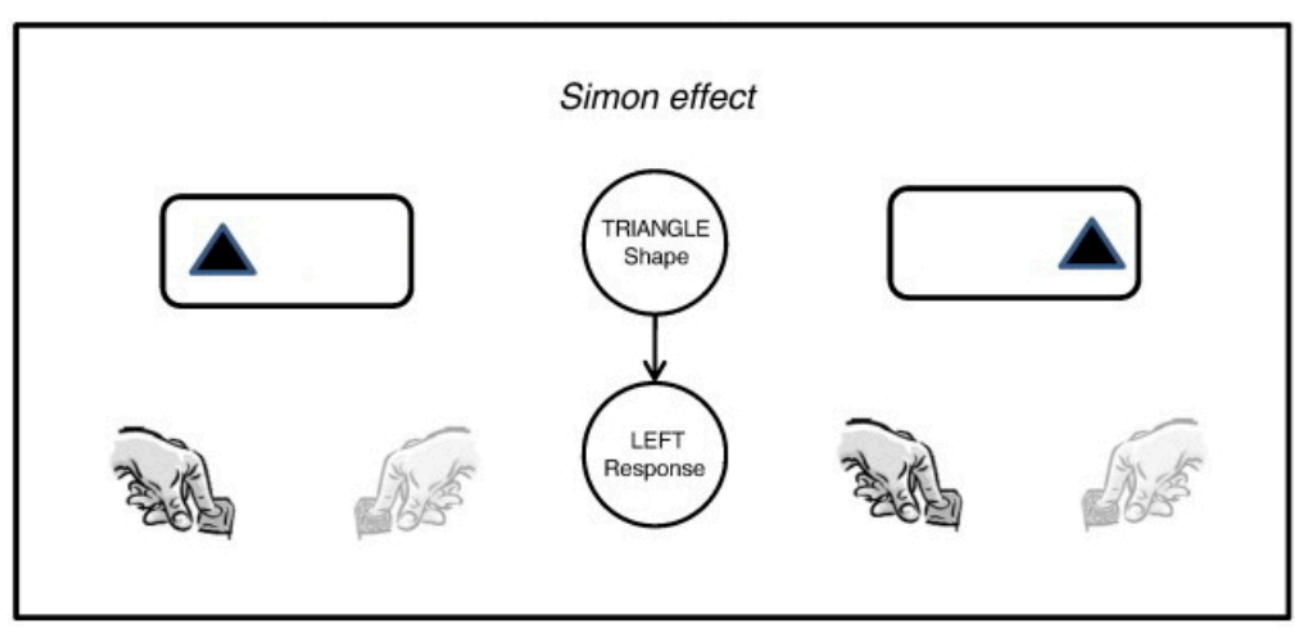

figure: http://sylvankornblum.com/the-simon-task/, experiment: https://www.psytoolkit.org/experiment-library/simon.html

Social Simon effect?

- How can we make the Simon task so that two people (not one) can perform together?

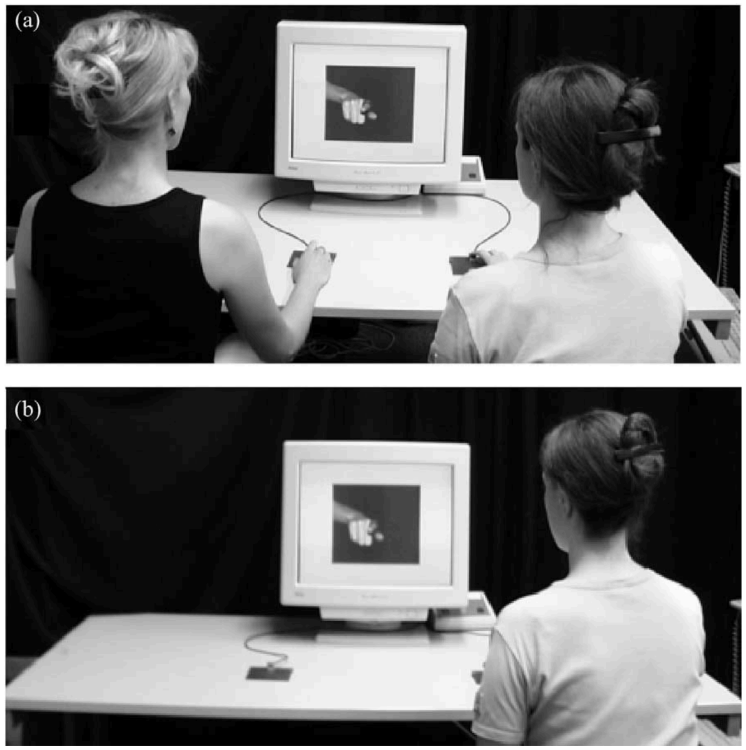

Fig. 1 Setting in the joint go-nogo task (a), and in the individual go-nogo task (b)

- What you have to do is only to respond to one stimulus (e.g., if a triangle, press the right button)
  - essentially this turns to be a go/no-go task
- a) Joint condition: you perform the task **with** your partner
- b) Individual condition: you perform the task **without** your partner

Representing others' actions: just like one's own? Sebanz et al., 2003

People are affected by their partner

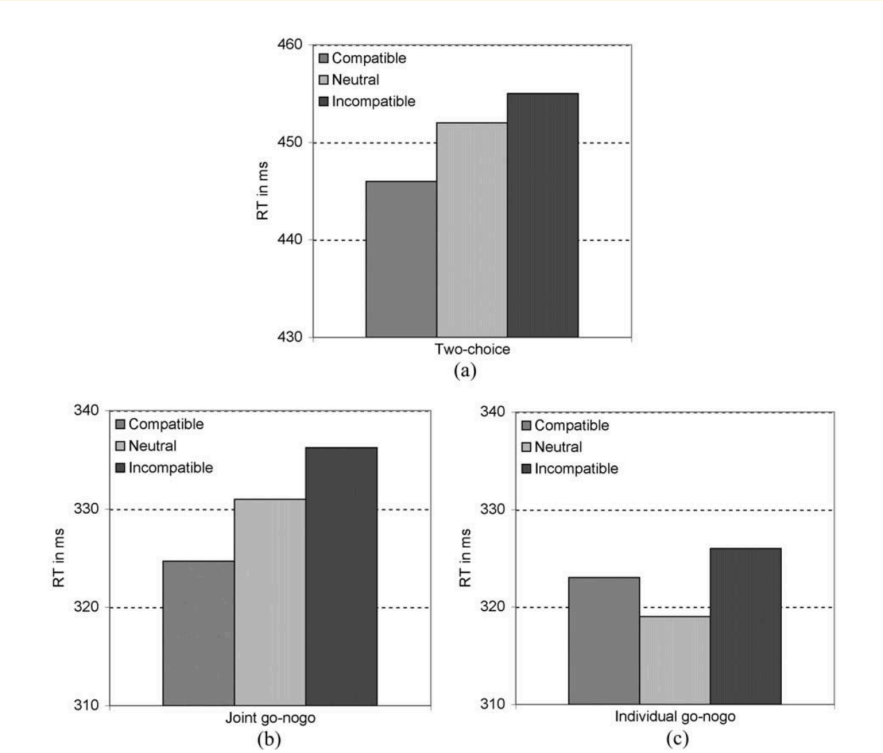

Fig. 2. Mean RTs on compatible, neutral, and incompatible trials in the two-choice condition (a), the joint go-nogo condition (b), and the individual go-nogo condition (c). Mean RTs in the two-choice condition were 446 ms (SD = 40 ms), 452 ms (SD = 40 ms), and 455 ms (SD = 43 ms), in the joint go-nogo condition 325 ms (SD = 32 ms), 331 ms (SD = 32 ms), and 336 ms (SD = 32 ms), and in the individual go-nogo condition 323 ms (SD = 32 ms), 319 ms (SD = 30 ms), and 326 ms (SD = 28 ms).

- Essentially one individual **always** needed to respond to one stimulus regardless of the conditions.
- Compatibility Effect (CE) = Difference between Compatible and Incompatible conditions
- **CE in Joint condition > CE in Individual condition**

Representing others' actions: just like one's own? Sebanz et al., 2003

Other findings

- Similar findings to Sebanz et al. (2003) using other compatibility tasks (e.g., Atmaca et al., 2011)
- Allocating attention differently when coactors are present (e.g., Böckler et al., 2012; Eskenazi et al., 2012)
- Neurocognitive evidence (e.g., Bekkering et al., 2009)
  - action monitoring
  - action prediction
  - action selection

Why do coactors matter?

- Automatic self-other integration?
- Performing with computers? Beliefs are enough?
- Representing coactors' tasks, or coactors or something else?

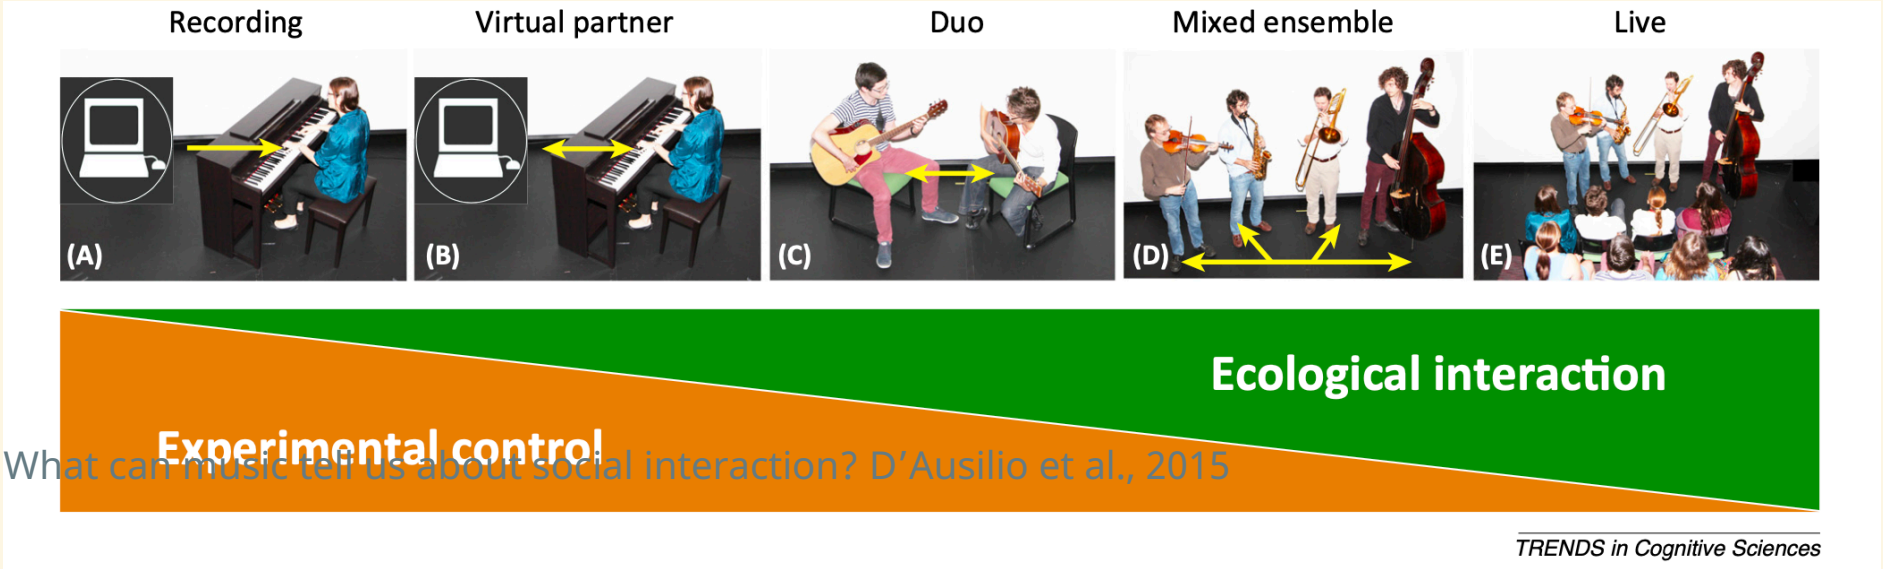
2. Music

unique human cultures

Music as a tool to investigate JA

Why is music useful to study JA?

- A **universal** way of non-verbal communication/coordination
- Multi-level interactivity: from individuals to groups
- Parent-infant synchrony to professional jazz improvisation
- Trade-off between experimental control and ecological validity



What can music tell us about social interaction? D'Ausilio et al., 2015

>> sidenote: is music universal across cultures?

- BBS (Behaviour and Brain Sciences) / one of the forthcoming topics is **the origin of music**

Music as a coevolved system for social bonding

Show author details

JA research in music

- **Temporal-auditory** coordination (**real-time** interactions)
  - relatively easier to measure (quantify) compared to sensorimotor coordination (e.g., body sway)
  - written information-flow between performers; namely sheet music!

Various topics

- Parent-infant synchrony
- Prosocial behaviour
- Real-time interpersonal coordination
- Leader-follower relationship
- Interpersonal brain synchrony

What can music tell us about social interaction? D'Ausilio et al., 2015

3. My research

teaching expertise

What am I doing?

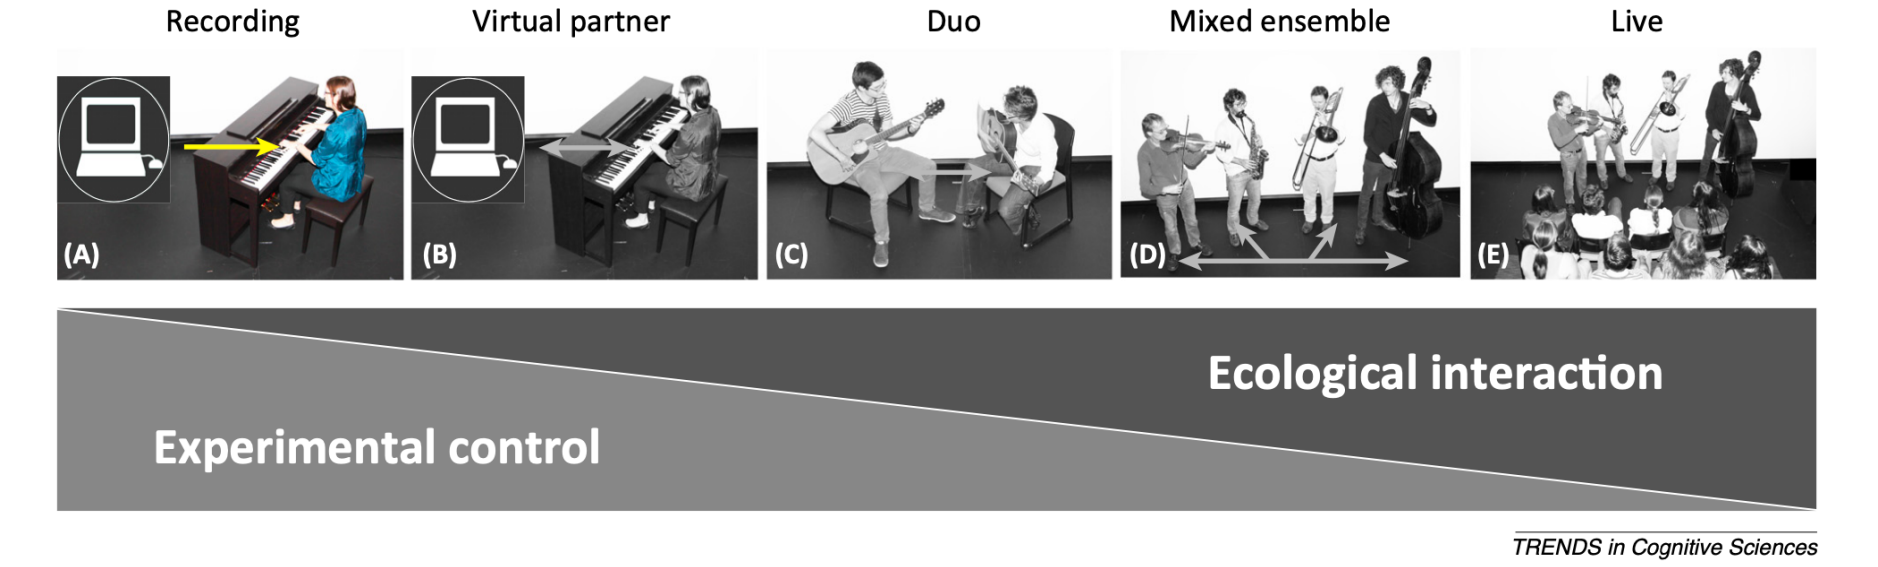
- Many forms of JAs - I am interested in **teaching behaviour**.
  - Knowledge between a teacher and a student is **not equal**.
- Teaching has been supposed to be unique to human beings (Tomasello, 2016; Whiten, 2017)
  - Ostensive signals (e.g., eye contact, pointing, infant-directed speech) alter what novices learn (e.g., Csibra & Gergely, 2009)

Do experts modulate their behaviour for teaching?

- Infant-directed speech and action (e.g., Wang et al., 2018; Brand et al., 2002)
- Slow and exaggerated performance
  - to attract novices
  - to show relevance to novices
  - any performance which is deviated from the optimal one is fine?

Teaching musical expressive techniques

- How about teaching expertise where subtle modulation is crucial to acquiring skills?



- Currently doing (A) - very controlled (non-interactive) experiments

Teaching musical expressive techniques

- Articulation (the smoothness of sound) Legato / Staccato

- Dynamics (the loudness of sound) Forte / Piano

Experiment

- Recruited expert pianists (more than 10 years experience in piano)
- Asked to perform one piece with either articulation and dynamics in the following conditions

Teaching condition

Perform the piece with a designated expressive technique to teach it to students (**as a teacher**).

Performing condition

Perform the piece with a designated expressive technique to perform your best to an audience (**as a performer**)

Experiment

Design (within-subjects)

- Condition: Teaching vs Performing
- Technique: Articulation vs Dynamics

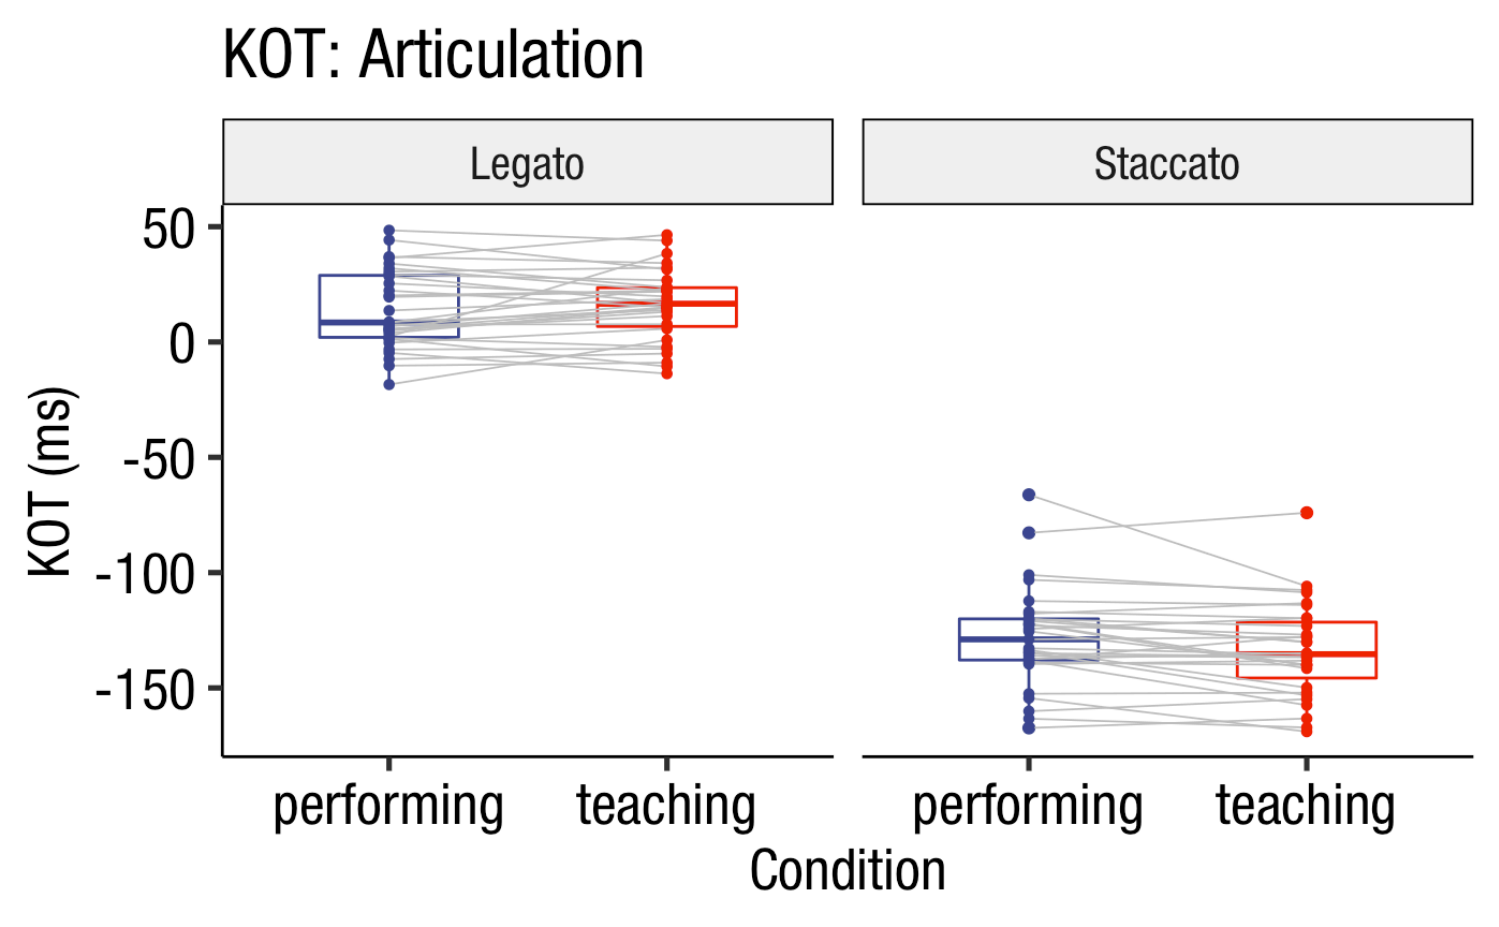
Hypotheses

- Experts will highlight the most relevant feature of the expressive technique they are going to teach.
  - exaggerate articulation (= **longer** legato and **shorter** staccato) when teaching
  - exaggerate dynamics (= **louder** forte and **softer** piano) when teaching

How to quantify musical performance?

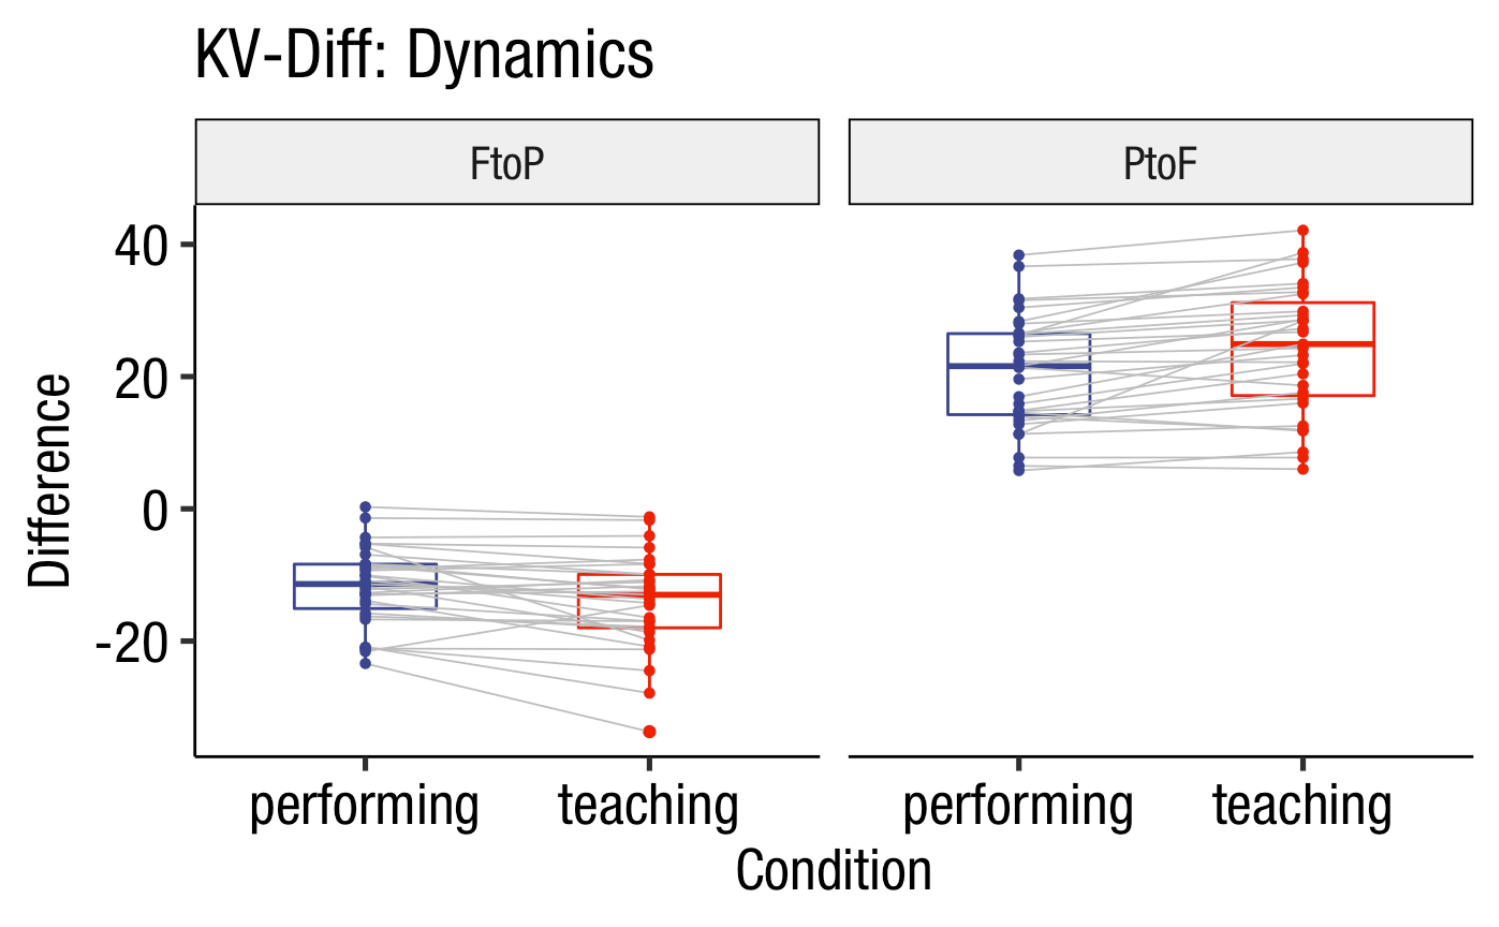
- From discrete to continuous measures
  - finger-tapping/drumming, keyboards: discrete
  - string, wind instruments etc.: continuous (more complex)
- MIDI data
  - **M**usical **I**nstrument **D**igital **I**nterface
  - timestamp of each onset / offset
  - pitch
  - velocity (loudness)
  - similar to reaction times (RTs) in Psychological Research

Results (teaching articulation)



- Participants highlighted staccato (= produced **shorter** staccato for teaching)

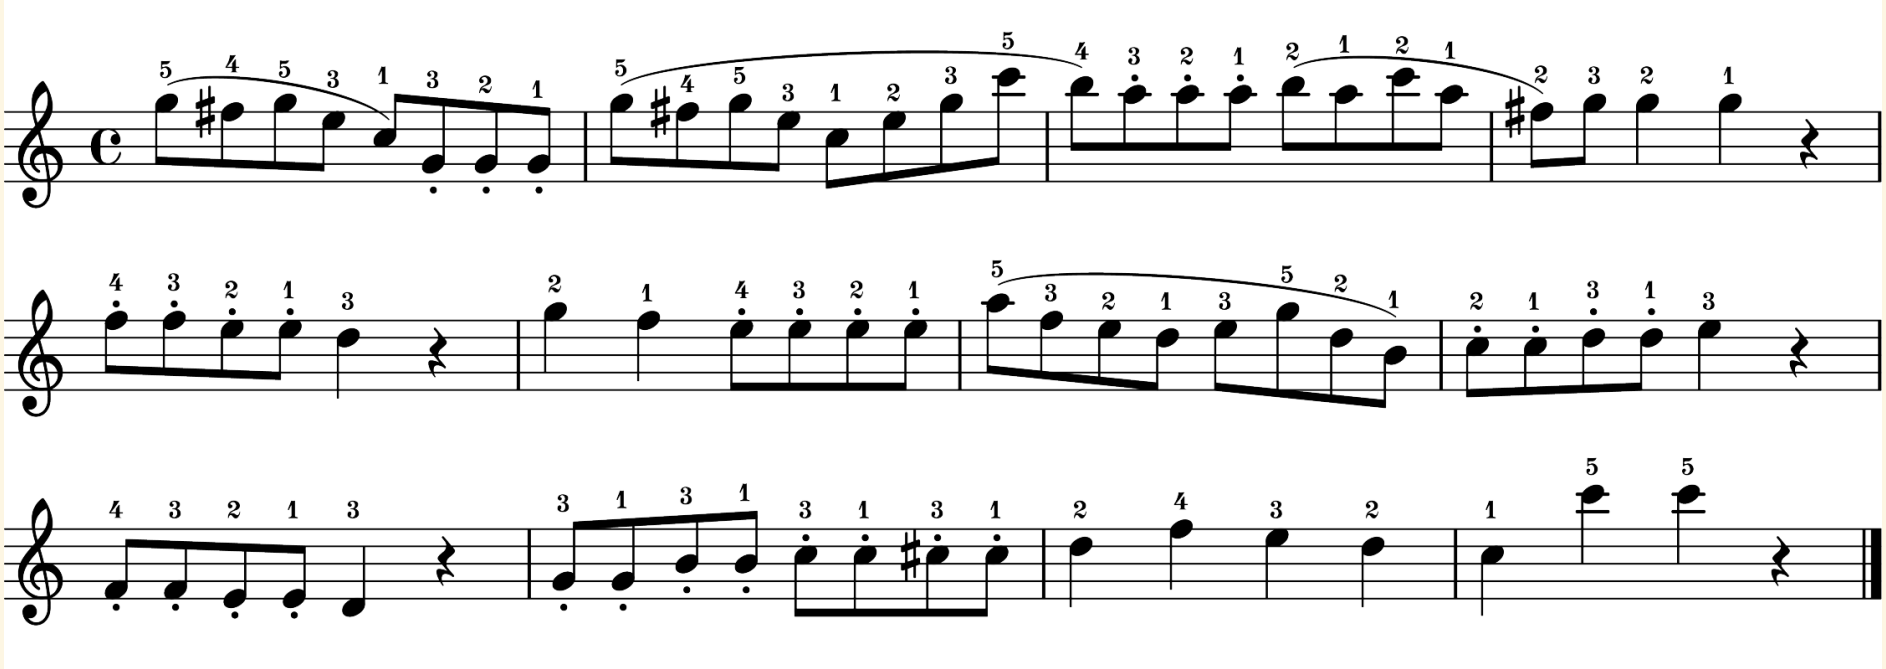
Results (teaching dynamics)



- Participants made a **larger** contrast between forte and piano for teaching

Replicated with a more naturalistic piece

- Clementi: Sonatina in C major, op. 36 no. 3 (modified)



Discussion

- Expert pianists successfully modulated their performances for teaching.
  - especially highlighting **the most relevant aspect** of the technique to be taught
  - not only overall exaggeration but also focusing on particular points (**fine-tuned** exaggeration)

Limitations

- Imaginary situation
  - Do they behave in the same way if they are in front of actual students?
- Lack of students' information
- Can students notice such exaggeration (because they are too subtle)?

Current study

- Looking at perceptual abilities of musicians and non-musicians for such modulation.

SOMBY Lab at CEU (Vienna)

SOcial **M**ind and **B**od**Y** Lab

- Principle Investigators: Natalie Sebanz and Günther Knoblich

- *Topics*: Joint planning, coordination, and commitment / Communication and teaching in joint action / Joint attention, perspective taking etc.
- *Methodologies*: Classical behavioural studies, motion tracking, eye tracking, EEG, musical equipments (e.g., keyboards, drum pads) etc.
- *Website*: https://somby.ceu.edu/

Any question?
